Crime Analysis

Multiple R-squared: 0.04019,

F-statistic: 21.1 on 1 and 504 DF, p-value: 5.506e-06

2023-08-27

WHAT IS THE PROBLEM ABOUT

This problem involves the Boston data set. Here, I am predicting per capita crime rate using the some of the variables in this data set. In simple words, per capita crime rate is the response, and the other variables are the predictors.

I HAVE DIVIDED THE PROJECT INTO SECTIONS SO THAT IT GIVES CLARITY TO THE VIEWER ON WHAT TO EXPECT IN EACH STAGE

OVERVIEW OF THE FIRST STEPS TAKEN

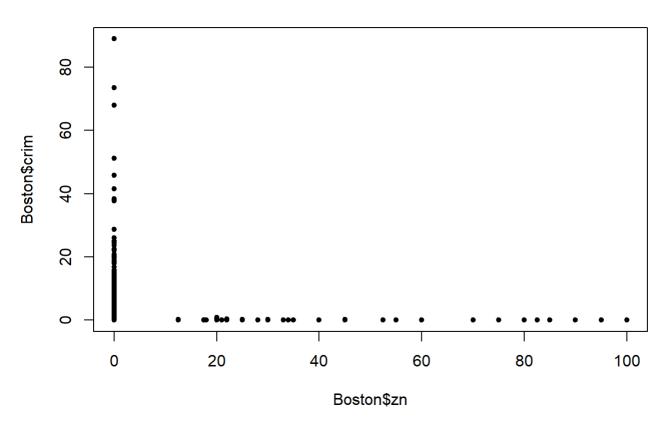

First, for each predictor, I will fit a simple linear regression model to predict the response. Then you can find my take on the results below. I will also mention in which of the models there is a statistically significant association between the predictor and the response. What will this do? Well, it will help us understand to choose the best model in similar datasets in the future with similar circumstances. Then finally, I will also create some plots to back up your assertions.

OVERVIEW OF THE NEXT STEPS TAKEN

I will fit a multiple regression model to predict the response using all of the predictors and then I will also write a small explanation of the results. Finally, I will determine for which predictors can we reject the null hypothesis H0 : $\beta j = 0$? What will it do, well it will help us determines which variables are important predictors.

#we see that the predictors "zn", "dis", "rad", "black" and "medv" are statistically significant becuase of their low p-value. Hence we can reject the null-hypothesis for these predictors.

OVERVIEW OF THE THIRD PART

Then comparing how the results from (a) compare to the results from (b)? Then I will create a plot displaying the univariate regression coefficients from (a) on the x-axis, and the multiple regression coefficients from (b) on the y-axis. That is, each predictor will be displayed as a single point in the plot. Its coefficient in a simple linear regression model will be shown on the x-axis, and its coefficient estimate in the multiple linear regression model will be shown on the y-axis.

```
#First lets create a vector with the coefficients of all the simple regression models in a.
simplecoef <- vector("numeric", 0)</pre>
simplecoef <- c(simplecoef, lm.fit1$coefficients[2])</pre>
simplecoef <- c(simplecoef, lm.fit2$coefficients[2])</pre>

#Now plotting,

plot(simplecoef, multiplecoef, col = "green", pch = 20, ylab = "Coefficients of multiple regression", x lab = "Coefficients of Univariate regression", main = "Plot between Multiple regression coefficients and Univariate regression coefficients")

ot between Multiple regression coefficients and Univariate regression coeff

explaining the first part of the question, we see that the coefficients in (a) or Univariate regression coefficients and the coefficients in (b) or multiple regression coefficients have a striking difference. We see that the according to multiple regression, per capita crime has almost no relationship with the a lot of the predictors if not all. However, in the simple regression it is not the case as there are association of per capita crime with a lot of predictors.

OVERVIEW OF THE NEXT PART

I am checking if there is evidence of non-linear association between any of the predictors and the response? To answer this question, for each predictor X, I will fit a model of the form $Y = \beta 0 + \beta 1X + \beta 2X2 + \beta 3X3 + \epsilon$.

```
#crim=60+61(zn)+62(zn)2+63(zn)3+\epsilon

#based on p-values, medv has a non-linear association with crim.

OVERVIEW OF THE NEXT SECTION

We will now try to predict per capita crime rate.

For that we will try out some of the regression methods, such as best subset selection, the lasso, ridge regression, and PCR. Then we will present and discuss results for the approaches that we consider.

#1) subset selection - exhaustive

#Comapring the results, we see that the linear model, Pcr and pls model perform similarly producing the same test error. The linear model here, performs a little better with all the predictors then with the best selected predictors. Overall, the ridge model here performs slightly better. However, the difference is negligible.

Now lets propose a model (or set of models) that seem to perform well on this data set, and justify my answer.

Here, I am Making sure that I am evaluating model performance using validation set error, crossvalidation, or some other reasonable alternative, as opposed to using training error.

So, I will propose Ridge model as it has a slightly lower test error than other models and as it also stabilizes the model and prevents overcomplicating. However, even Lasso can be considered depending on the requirement and context as it also produces low test error. But since here no context or requirement is mentioned, I am proposing Ridge based on its lowest test_error values observed. Hence the best model to predict college applications is Ridge. Following it will be the Lasso model. This evaluation has been made by performing cross-validation and validation set error as that is how the test error values were obtained.

Again, does my chosen model involve all of the features in the data set, let see

Well Ridge Regression, the chosen model, does use all the features (predictors) in the dataset. Ridge Regression uses a technique called L2 regularization, which penalizes the model based on the square of the coefficients. Unlike Lasso, Ridge doesn't force coefficients to become zero aggressively. Instead, it reduces their impact, helping to stabilize the model and avoid overfitting. Ridge usually includes all the features in the model but manages their influence to create a more balanced and reliable prediction preventing any single feature from dominating the prediction. This ensures a more stable and less prone to overfitting model. It is more about finding the right balance between the best predictors.
